NIX / CORE BY ZIA

Executive architecture

One prompt. Isolated applications. One host display.

Core is the operating system. NIX is the experience you use to ask for work, open applications, and see results. Local AI turns requests into controlled actions while Core manages the computer and keeps application environments separate.

How it works

Ask NIX to open an application. A native app runs directly through Core services. Most non-native apps receive their own small virtual computer with a Linux 7.3.1 kernel, memory, and app dependencies. Windows software runs in a Windows guest.

The NIX compositor combines native and guest pictures on the host display and sends your input to the correct app. Desktop OpenGL 3.0 is the graphics baseline. Shared frames come first; GPU buffer sharing adds acceleration where supported.

Build direction for Codex

Implement Core isolation and services, then the native display, then QEMU and one Linux guest per app. Connect guest pictures and input to NIX. Add graphics acceleration, Windows compatibility, and local AI launch control. Verify each layer before adding the next.
